

System Health Monitoring and Application Health Checker using Python

Objective: To monitor system performance (CPU, memory, disk usage) and check application availability using HTTP status codes.

Tools Used: Python, psutil library, requests library

1. System Health Monitoring Script

The system health monitoring script checks CPU usage, memory usage, and disk usage of the system. If any of these values exceed predefined thresholds, alerts are logged into a file with timestamp for analysis.

2. Application Health Checker

This script checks whether a web application is UP or DOWN by sending HTTP requests. It verifies the status using HTTP response codes and logs the results for monitoring purposes.

Conclusion: The project successfully demonstrates system monitoring and application health checking using Python automation scripts.
